POWER BI RETAIL SALES AND FINANCIAL PERFORMANCE

Dashboard Analysis Report

Student Name	Akshaya
Course	B.Com FinTech with AI
Report Title	Power BI Retail Sales Dashboard Analysis
Data Source	Power BI report screenshots supplied for analysis
Date	11 November 2026

Prepared as an academic report based on the three Power BI pages provided. The report uses written analysis only; dashboard screenshots are not reproduced.

CONTENTS

1. Introduction
2. Dashboard Overview
3. KPI Analysis
4. Store and Store-Type Analysis
5. Product Category Analysis
6. Monthly Revenue Trend
7. City-Wise Revenue Analysis
8. Business Insights
9. Business Recommendations
10. Limitations and Data Notes
11. Conclusion

Note: Values are reported as displayed on the dashboard. Where chart labels or exact values are not readable, the discussion is kept descriptive rather than assigning unsupported figures.

1. Introduction

This report examines a retail sales and financial performance dashboard created in Microsoft Power BI. The dashboard brings together key business measures such as revenue, costs, profit, quantity sold and transaction volume. It also compares performance across stores, store types, product categories, months and cities.

The purpose of the analysis is to explain what the dashboard indicates about the business. It looks at the headline figures first and then considers the patterns shown in the charts. The final sections identify useful business insights and suggest actions that could help management improve sales performance and reporting.

1.1 Objectives

- To summarise the main sales and financial performance indicators.
- To compare revenue across stores and store types.
- To identify the product categories contributing most to revenue and profit.
- To review the monthly revenue pattern and city-wise performance.
- To present practical recommendations based on the dashboard.

1.2 Scope of the report

The analysis is limited to the information visible in the three supplied Power BI screenshots. The report does not assume access to the underlying Excel or database records. Exact values are used for KPI cards, while chart comparisons are described in general terms where the labels are too small or values are not displayed.

2. Dashboard Overview

The Power BI report contains three pages: KPI, Dashboard and Tool Tip. The KPI page presents the headline measures and charts. The Dashboard page provides an interactive view of the same sales information. The Tool Tip page contains a compact group of KPI cards that can provide additional information when a user interacts with a visual.

2.1 Main dashboard components

- KPI cards: Total Costs, Average Unit Price, Total Quantity, Total Revenue, Total Transactions and Total Profit.
- Store analysis: revenue by store name and revenue by store type.
- Category analysis: revenue by category and profit by category.
- Time analysis: monthly revenue across the displayed year/month sequence.
- City analysis: revenue compared across city names.

2.2 Interactive use

The visuals are designed to support interactive exploration. Selecting a data point in one chart can help the user examine related information in the other visuals. This makes it easier to compare the contribution of a particular store, category or city instead of relying only on the overall totals.

The screenshots show the report layout and its visual structure. They do not show a complete set of slicer selections or detailed filter settings, so this report does not make claims about specific filtered results.

3. KPI Analysis

The KPI cards provide a quick summary of the business's overall performance. The values visible on the dashboard are presented below.

KPI	Displayed value	Meaning
Total Costs	4bn	Total costs recorded in the report.
Average Unit Price	41.99K	Average selling price per unit, as labelled.
Total Quantity	112K	Total quantity sold.
Total Revenue	4.71bn	Total sales revenue.
Total Transactions	15K	Number of transactions recorded.
Total Profit	979.89M	Total profit shown by the dashboard.

3.1 Interpretation of the KPIs

Total revenue is displayed as 4.71bn, while total costs are shown as 4bn. The dashboard also reports total profit of 979.89M. These figures indicate a sizeable level of business activity. The quantity card shows 112K units and the transaction card shows 15K transactions, suggesting that the report covers a substantial volume of sales.

The average unit price is 41.99K. When considered alongside the total quantity of 112K, this gives a broad indication of the scale of sales. However, the dashboard does not display the currency or the precise calculation definitions, so the figures should be interpreted using the labels provided rather than assuming a particular currency.

3.2 KPI check

A simple subtraction of the rounded KPI values gives 4.71bn in revenue minus 4bn in costs, or approximately 710M. This is different from the displayed total profit of 979.89M. The difference may be due to rounding, different measure definitions, or additional adjustments in the profit calculation. The underlying measures should be checked before the figures are used in formal financial reporting.

4. Store and Store-Type Analysis

The dashboard includes a horizontal bar chart showing total revenue by store name. The bars are not identical in length, which indicates that revenue differs across the listed stores. Several stores appear close to one another, while some have lower revenue. This comparison can help management identify stores that are performing strongly and those that may need further review.

A doughnut chart compares revenue by store type. The legend includes Urban, Flagship, Mall, Online and Suburban, as well as a separate lower-case 'urban' label. The chart shows that revenue is distributed across more than one store type rather than coming from a single channel.

4.1 Interpretation

- Store-level differences can be used to compare sales performance and identify locations for closer review.
- The store-type chart provides a channel-level view of revenue and can support decisions about store formats.

- The labels 'Urban' and 'urban' appear separately. If they represent the same store type, the category values should be standardised in the source data.

The chart does not provide clearly readable exact revenue values for every store or store type. Therefore, this report does not assign precise amounts or rankings beyond what can be seen from the relative bar and segment sizes.

5. Product Category Analysis

Product performance is presented through two visuals: total revenue by category and total profit by category. The revenue bar chart shows Mobile Phones as the largest category, followed by Laptops and Televisions. Home Appliances appears next, while Audio, Wearables and Accessories contribute smaller amounts in the displayed chart.

The treemap for total profit shows a similar broad pattern. Mobile Phones and Laptops occupy the largest areas, with Televisions and Home Appliances also making visible contributions. Smaller blocks represent categories such as Audio and Wearables. The size of each block represents its relative contribution to the profit measure.

5.1 Interpretation

Mobile Phones and Laptops are important categories in the dashboard because they occupy the leading positions in the revenue chart and large areas in the profit treemap. These categories deserve attention when planning stock levels, promotions and product availability. The smaller categories should not automatically be removed; management should also consider their margins, customer demand and role in attracting customers.

A useful next step would be to compare revenue, cost and profit for each category in one table. This would show whether a category with high revenue also produces a strong profit margin.

6. Monthly Revenue Trend

The line chart titled Total Revenue by month_name and Year displays revenue over a sequence of months. The line moves up and down during the period. It includes increases and decreases rather than showing a continuous rise or fall. This indicates that monthly revenue varies over time.

6.1 Interpretation

The changes in the line may reflect differences in customer demand, promotions, seasonal buying patterns or product availability. These are possible explanations, not confirmed causes, because the screenshots do not provide supporting information about campaigns, stock levels or customer behaviour.

To understand the trend more clearly, management could compare the same month across different years and add labels for major sales events. A date hierarchy with clearly identified months and years would also make the chart easier to interpret.

7. City-Wise Revenue Analysis

The dashboard contains a bar chart comparing total revenue by city name. The bars show differences in revenue across the listed cities. Some cities have visibly higher bars, while the remaining cities form a group with comparatively smaller and closer values.

7.1 Business use

- Compare sales performance across cities to identify stronger and weaker markets.
- Review stock availability and product demand in cities with lower revenue.
- Study customer preferences and local competition before planning city-specific promotions.

The city labels and bar heights are not sufficiently clear to report exact values for each city. A detailed export from Power BI would be required for an accurate city ranking.

8. Business Insights

Dashboard observation	Business insight
Revenue is shown as 4.71bn and profit as 979.89M.	The business reports a substantial sales and profit total, but the profit calculation should be reconciled with costs.
Total quantity is 112K and transactions are 15K.	The dashboard indicates a high volume of sales activity.
Mobile Phones and Laptops lead the category visuals.	These categories are important contributors and should be monitored for stock and profitability.
Revenue differs across store names and store types.	Store performance can be compared to identify areas for operational improvement.
Monthly revenue moves up and down.	Sales are not identical from month to month; the causes of variation should be investigated.
City-wise bars have different heights.	Sales performance varies by city, creating opportunities for targeted local action.
The legend includes both 'Urban' and 'urban'.	Category naming may need cleaning to avoid splitting one group into two.

9. Business Recommendations

- Check financial measures: Review the definitions of Total Costs, Total Revenue and Total Profit. Confirm why the displayed profit differs from the simple difference between rounded revenue and costs.
- Focus on leading categories: Monitor the availability, pricing and profit contribution of Mobile Phones and Laptops, while continuing to review the performance of smaller categories.
- Compare store performance: Use store-level revenue and profit together to identify stores that need support and stores whose practices may be useful elsewhere.
- Review store-type performance: Compare physical and online store types to understand which channels contribute most to revenue.
- Investigate monthly changes: Compare month-on-month and year-on-year results and relate major changes to promotions, seasonal demand and stock availability.
- Plan by city: Use city-level results to guide inventory distribution and local marketing, after confirming exact values from the underlying data.
- Improve data consistency: Standardise category names such as 'Urban' and 'urban' and ensure all chart labels are clear.

- Improve dashboard readability: Display data labels, currency units, date ranges and definitions for each KPI so users can understand the figures without guessing.

10. Limitations and Data Notes

- The analysis is based on three screenshots of the Power BI report, not on the underlying dataset.
- KPI values are quoted as displayed and may be rounded by Power BI.
- Exact values for individual stores, store types, categories and cities are not clearly readable in the screenshots.
- The currency and reporting period are not explicitly stated in the visible dashboard area.
- The difference between revenue minus costs and the displayed profit requires clarification from the source measures.
- The monthly line chart shows variation, but the screenshots do not establish the reasons for the changes.
- The report does not include customer-level information, product-level detail or explanations for business events.

These limitations mean that the report is suitable for a descriptive review of the dashboard, but not for a full audit of the business's financial results. More detailed analysis would require access to the Power BI model or exported source data.

11. Conclusion

The Power BI dashboard provides a useful overview of retail sales and financial performance. It reports total revenue of 4.71bn, total costs of 4bn, total profit of 979.89M, total quantity of 112K, average unit price of 41.99K and 15K transactions. The charts allow users to compare performance across stores, store types, product categories, months and cities.

The category visuals identify Mobile Phones and Laptops as major contributors, while the store and city charts show differences across business locations and channels. Monthly revenue also changes during the displayed period. These patterns can support decisions about inventory, marketing and store operations.

Before using the dashboard for important business decisions, management should confirm the profit calculation, standardise category labels and review the exact values behind the charts. With these checks and clearer labels, the dashboard can become a more reliable tool for monitoring sales and supporting business planning.
